

IoT Project Idea

By Shreyas Palley, Keshav Gupta, Akshat Sanghvi, Vrinda Agarwal

Overall objective

For our IoT project, we wanted to address and tackle common problems observed among many students across the IIIT campus as well as provide a working, practical solution that can be used by all.

This problem is the availability of washing machines and western bathrooms. Students often have to manually check if the western toilets and washing machines are available and often end up wasting lots of time, especially in the morning before classes for toilets and evenings for clothes. We decided to optimize this task by providing the availability of both western toilets and washing machines via a quality of life web/mobile app, which displays the live data that can be conveniently viewed on any device.

In addition to this, for the toilet, there are many cases where the toilets are not flushed after use. Hence, we can use this IoT device to automatically flush the toilet after sensing when one leaves.

What are the inputs/physical quantities measured?

1. **Ultrasonic sensor** to measure distance of door from object of reference (wall).
2. **Motion Sensors** to track when someone enters or leaves the bathroom stall.
Also measure rotation motion of washing machine.

How are you going to use the input?

For the toilet, the **ultrasonic sensor** will be able to calculate the distance of the wall from the door such that if the distance is less than the actual distance from door to wall, then it will output that the door is currently open, else the door is currently closed. We will use the **motion sensors** in coordination with the ultrasonic sensor to reaffirm this output data by sensing whether or not someone enters or leaves the bathroom stall, further ensuring that the output data produced is accurate and reliable. After someone leaves, measured by the door-to-wall distance being less than when the door is closed as well as motion sensor tracking someone leaving, a **servo motor** will be implemented to flush the toilet after use.

For the washing machines, a **motion sensor** will be implemented to view whether the clothes in the washing machine are being rotated, signaling its use.

Description of the output

Taking the data of whether a bathroom stall and washing machine is in-use or not, we send this data to our server. We then utilize this data by creating a web/mobile app to display the status for all bathroom stalls and washing machines, giving a useful overview of their current real-time availabilities.

In addition to this, we will also obtain the time ranges of when the bathroom stall was occupied and when it is empty. This can help produce relevant data analysis such as histograms, time frequency charts, etc.

In this data analysis, we would also observe the floor by floor data as well as the most common times in the day that the washing machines and bathrooms are used such that people can figure out which western toilet or washing machine is available before wasting their time to manually check.
